Apparatus For Testing Co-efficient of Friction of a Road Surface

This invention relates to U.S. Provisional application Serial number 60/230,360, filed Sept. 6, 2000.

TECHNICAL FIELD

9 This invention relates to testing apparatus and in particular to an
10 apparatus that provides for an accurate and precise indication of the co-
11 efficient of friction on a road's surface from a gauge- reading in the
12 apparatus which indicates the coefficient of friction of a road's surface to
13 rubber on a rubber tire of a moving vehicle on the road.

15 Background To The Invention

17 The highway department of the State of California, CalTrans, has
18 used an apparatus of this kind since the 1960's, and this apparatus is an
19 improvement over the CalTrans apparatus. This apparatus is unique in the
20 sense that no other device of this nature is known except the old one of
21 CalTrans and this improvement over it..

23 The needs the invention addresses and satisfies in this kind of
24 apparatus are increased dependability, accuracy, and ease of operation.

25 Summary of The Invention

27 The invention is in an apparatus, stationary in operation, that pro-
28 vides accurate measurement of speed and control by a digital speed control
29 in electronic control circuitry on a rotating tire through its sensor, to sense
30 the tire speed. An accurate, precise reading of the coefficient-of-friction
31 of a road's surface is achieved. A mechanism trips a cocked bell-crank
32 assembly that includes a bearing that is freed from its cocked position by
33 an energized solenoid with the action of which simultaneously drops the
34 rotating tire upon the road surface being tested. A digital electronic control
35 circuit manually initiated conducts the test automatically.

36

1
2 An object of this invention is to provide a dynamic testing reading
3 from an apparatus in a static environment, such as standing in a stationary
4 manner, without the need for the testing apparatus to be moving along a
5 roadway.

6

7 Another object of the invention is to provide for an automated
8 operation of an apparatus that tests for co-efficient of friction of a road
9 surface.

10

11 A further object of this invention is to provide substantial savings in
12 the cost of conducting a co-efficient-of-friction test by the apparatus of this
13 invention.

14

15 A still further object of this invention is to provide portability for
16 positioning at various stationary locations the apparatus and by which it
17 is ready with ease for immediate operation in a next stationary location.

18

19 These and other objects and advantages of the invention will
20 become more apparent upon a full and complete reading of the following
21 description, the appended claims thereto and the accompanying drawing
22 comprising seven (7) sheets of ten (10) FIGURES.

23

24 BRIEF DESCRIPTION OF THE DRAWING

25

26 FIG. 1 is a plan view of the apparatus of this invention, in its cocked
27 or O-position.

28

29 FIG. 2 is an elevational view of the apparatus taken on line 2 - 2
30 of FIG. 1, the apparatus in its cocked or O-position.

31

32 FIG. 2A is an enlarged fragmentary diagrammatic view taken at the
33 end of line 2A in FIG. 2, illustrating a toothed sprocket wheel on the shaft
34 of a motor in the apparatus and its pulley belt.

35

36 FIG. 2B is an enlarged fragmentary diagrammatic view taken at the
37 end of line 2B in FIG. 2, illustrating a tire axle's sprocket wheel to which

1 the pulley belt illustrated in FIG. 2A is applied.

2

3
4 FIG. 2C is an enlarged end view of a tire on which a flat portion is
5 illustrated on the tire's periphery or greatest radius from the axis of a wheel
6 on which the tire is securely mounted.

7

8 FIG. 3 is a rear elevational view of the apparatus taken on line 3
9 - 3 of FIG. 2, in a mode in which its rotating tire is not in contact with a
10 road surface.

11

12 FIG. 4 is a front elevational view of the apparatus of FIG. 3.

13

14 FIG. 5 is a rear elevational view of the apparatus in a mode in which
15 its rotating tire is in contact with a road surface.

16

17 FIG. 6 is a plan view of the apparatus of the invention in a mode at
18 or after the tire has engaged a road surface.

19

20 FIG. 7 is a schematic drawing of the electronic control circuit for
21 operation of the automated apparatus.

22

23 BEST MODE FOR 24 CARRYING OUT THE INVENTION

25

26 Referring now to the drawing wherein reference characters correspond
27 to like numerals hereinafter in the following description, FIGS. 1 - 6
28 illustrate an apparatus 20 embodying the invention. FIG. 7 illustrates an
29 electronic circuit 22, FIG. 7, for operating apparatus 20. Apparatus 20,
30 FIGS. 1, 2, 6, includes a frame 24 formed by a pair of spaced tubular
31 members 26 each of which, at the front end of apparatus 20, is fixed in
32 relationship to each other by their ends being securely mounted in their
33 corresponding bores 27 which are in stepped-up parts of a solid one-piece
34 metal casting 28. A pair of spaced upright angled-iron members 29 are
35 fixed to the front wall 30, FIG. 1, of casting 28. An electronic control
36 console 31 is fixedly supported by a pair of rigid arms 32 securely
37 mounted to the rearward sides of upright members 29 and in which

2 elements of circuit 22 are disposed, with the collection of the circuit's
3 wirings 33, FIGS. 2, 3, 4, 5, 6, emanating from various points of the
4 console's housing to, for example, a motor 34, FIG. 1, 2, and to their other
5 corresponding elements in FIGS. 1, 2, 3, 5, 6, by which apparatus 20 is
6 energized for operation. A hitch assembly 35 is securely mounted to
7 the forwardly extending sides of and between upright members 29 and
8 by which apparatus 20 is held stationary during a testing operation. Front
9 swivel caster assemblies or standards 36 are suitably located exteriorly,
10 FIGS. 1, 4, of tubular members 26, each being securely fixed to the
11 underside 37, FIG. 2, of solid casting 28 and by which ease of portability
12 from one stationary point to another for apparatus 20 is provided.

13

14 At the rear end of apparatus 20, FIGS. 1, 2, 3, each of tubular
15 members 26 is suitably securely mounted in bores 38 formed in a rigid
16 metal casting 39 and by which tubular members 26 remain in planar and
17 parallel orientation in their spaced relationship. Metal casting 39 projects
18 laterally beyond each tubular member 26 for a fixed mounting adjacent
19 each of its ends of constant-force coiled spring assemblies 40. Open ends
20 of the springs in assemblies 40 are correspondingly suitably connected or
21 hooked by springs assemblies 42 to their respective transversely extending
22 brackets 44, FIG. 1, 2, securely fixed to an underside 45 of their
23 corresponding spaced rectangular tubings 47 of and extending
24 longitudinally within a carriage 48 at equally distanced points along its
25 length. FIGS. 1, 2, 3, 6.

26

27 In carriage 48 the opposite ends of tubings 47 are securely
28 mounted in bores (not called out) formed in front and rear cross-struts 54,
29 FIG. 1; 6, of carriage 48. Cross-struts 54 include integral extensions 56
30 extending laterally beyond tubings 47 and in which bores 58 are formed.
31 Bearing carriers 59 for carriage 48 are slidably mounted on tubular
32 members 26 and are securely attached to the four (4) cross-struts 54 for
33 sliding and reciprocating carriage 48 along frame 24 in the operation of
34 apparatus 20.

35

Generally midway of the length of and in the space between tubings
47 and spaced cross-struts 54, an air-filled rubber tire 60, having a

1 sufficiently wide flat width or flat 61, FIG. 2C, for testing purposes in its
2 periphery or greatest radius, is disposed. Tire 60 is conventionally
3 mounted to its wheel 62, FIG. 2 that is rotatable with its axle 63
4 maintained outside the plane of tubings 47 and cross-struts 54 by it being
5 rotatably mounted in depending brackets 64 securely mounted on each of
6 tubings 47, FIG. 2. FIG. 2 illustrates the axis of axle 63 being below the
7 plane of tubings 47 and cross-struts 54. An electrical clutch 65, FIGS. 2,
8 6, is securely mounted adjacent the one end of axle 63, FIGS. 2, 6, along
9 with a sprocket wheel 67, FIG. 2B, suitably securely mounted on axle 63
10 to the interior side of electrical clutch 65. Sprocket wheel 67 includes
11 teeth 68, FIG. 2B, which cooperates with a toothed pulley belt 69 that
12 extends to and which cooperates with teeth 70 on a sprocket wheel 71
13 suitably secured to a shaft 72, FIG. 2A, of motor 34 and by which
14 combination a synchronous relationship is established.. Motor 34 is
15 securely mounted on a support base 73 securely mounted on a spacer
16 member 74 which in turn is suitably securely mounted to the tubings 47
17 of carriage 48. It should be understood that in the testing operation of
18 apparatus 20 that the collection of wirings 33 which extends between
19 console 31 and elsewhere along apparatus 20, for example, to motor 34,
20 is of flexible insulated nature and are harnessed together or otherwise
21 safely secured along the length of apparatus 20 out of the way of
22 movement of carriage 48 and motor 34 to prevent interference of such
23 wirings with any element of apparatus 20 that is in motion in its testing
24 operation.

26

27 Immediately next to teeth 70 of sprocket wheel 71, FIG. 2, a
28 timing sensor 75 is employed to count the number of teeth 70 that passes
29 it in a given period of time. Sensor 75 is suitably fixed on the end of the
30 housing of motor 34 in its location in proximity to teeth 70. The motion of
31 teeth 70 passing in proximity to sensor 75 generates a signal in the sensor
32 which is transmitted by the wiring 33 to Central Module CM1, # 17 in FIG.
33 7, which processes that signal and compares the rotational speed
34 corresponding to that signal to the programmed value within CM1 and
35 corresponding to the rotational speed of tire 60 required by the apparatus
36 20, to obtain accurate and precise results indicating the correct co-efficient
37 of a road surface 78 of road 79. FIGS. 2A, 2B diagrammatically illustrate

1 the teeth 68, 70 in the operation of apparatus 20. In the preferred
2 embodiment, 22 teeth are the actual number of teeth 70 on sprocket 71
3 about the motor's shaft 72 and 30 teeth are the actual number of teeth 68
4 on sprocket 67.

5

6 At the rear of and in the operation of apparatus 20, a mechanism
7 80, FIGS. 1, 2, 3, is provided to trip or release tire 60 from its elevated
8 position above road surface 78 as it is rotating at its appropriate and
9 measured speed in the testing operation upon road 79. Mechanism 80,
10 FIG. 3, includes a bell-crank assembly 81 to one end of which is attached
11 a roller bearing 82 of which seats upon a ledge or latch 83 in a cocked
12 position for mechanism 80. Ledge or latch 83 is formed on an outwardly
13 extending element 84 of a sleeve 85 threaded to a threaded stem 86
14 supported in a block 86b formed in casting 39 at the bottom of which a
15 swivel caster assembly 87 or standard is securely mounted its caster wheel
16 88 adapted for engaging the road surface 78 in the testing operation.
17 Assembly 81 includes an arm 90 connected to roller bearing 82 which is
18 pivotally mounted, as at 91, FIG. 3, to metal casting 39 of frame 24, below
19 ledge 83, arm 90 extending in its length to join linkage 92 that is attached
20 to the shaft of or a pull rod or shaft 93 of a solenoid 94 its housing captured
21 in an opening of L-shaped bracket 95 securely mounted to a support bar 96
22 that in turn is securely mounted to metal casting 39 of frame 24. Pull rod
23 or shaft 93 retracts in the apparatus' operation to uncock or release roller
24 bearing or latch 82 from ledge or latch 83, by the pivoting action at pivotal
25 mount 91 on arm 90, and thereby provide for the simultaneous dropping of
26 the entire rear end 97 of apparatus 20 pivotal at the axles of caster ass-
27 emblies or standards 36, and by which tire 60 drops onto road surface 78.
28

29

30 A span 98, FIGS. 2, 4, of distance between flat 61 and road surface
31 78 must exist in the cocked position and condition for mechanism 80, for
32 apparatus 20 to properly operate. With tripping mechanism 80 first placed
33 in its cocked position and condition, and (rear) caster assembly 87engaging
34 a point or patch on road surface 78 at which testing is to take place, handle
35 89 on threaded stem 86 is turned to lower or raise mechanism 80 towards
36 or away from road surface 78, thereby changing span 98 until it is properly
37 set. The action of turning handle 89 to properly set span 98 carries with it

1 the lowering and raising of frame 24 by reason of its connection to
2 mechanism 80 through (rear) metal casting 39, support bar 96 secured to
3 metal casting 39, solenoid 94 in support bar 96, and bell-crank assembly
4 81 connected to solenoid 94 as described above.

5

6
7 It should be noted in FIG. 3, that although caster wheel 87 is
8 engaging road surface 78 tire 60 is not, while in FIG. 5, tire 60 is engaging
9 road surface 78 as a result of the uncocking of mechanism 80 through the
10 release of end or roller bearing 82 from ledge or latch 83 which occurs in
11 the operation of apparatus 20, more fully described hereinafter. To place
12 apparatus 20 in its cocked position or condition, i. e., raising roller bearing
13 or end 82 so it grips ledge or latch 83, a lifting knob 100, FIG. 6, secured
14 to (rear) metal casting 39 for cocking mechanism 80, is grasped to raise
15 frame 24 so that the bell-crank assembly's end or roller bearing 82 seeks
16 and seats on ledge or latch 83 as lifting knob 100 raises frame 24.

17

18 In a cocked mode for apparatus 20, i.e, apparatus 20 is in an O-
19 position, FIG. 1, carriage 48 is at its rearward location in frame 24, bearing
20 carriers 59 adjacent to metal casting 39, a resilient or rubber stop 101 is
21 securely mounted centrally of rear cross-strut 54. A like resilient or rubber
22 stop 102 is securely mounted centrally of metal casting 39 of frame 24 and
23 abuts stop 101. Further, a hydraulically-actuated piston rod 104, FIGS. 1,
24 2, 3, of a hydraulic cylinder 105, projects through a hole 106 formed in a
25 rectangular metal member 107, FIG. 3, that is bolted to metal casting 39.
26 A door 108 is provided for hole 106, it being an extension of one of two
27 ears 109 having its door-operating lever 110, FIG. 3, pivotally mounted
28 at 111 to metal member 107. As illustrated in FIG. 3, door lever 110 is in
29 its upper position against the action of a spring 112 which otherwise biases
30 door 108 across hole 106. By manually holding lever 110 in its upper
31 position, wherein its action acts against the bias of spring 112, door 108 is
32 pulled from across hole 106, hole 106 is opened, and piston rod 104
33 projects through hole 106, and the resilient stops 101, 102 seat against each
34 other. When carriage 48 shoots forward on frame 24 in the operation of
35 apparatus 20, piston rod 104 and its hydraulic cylinder 105 go with it. As
36 soon as piston rod 104 passes back through hole 106, the biasing action of
37 spring 112 closes door 108 over it. In the reaction occurring upon

1 completion of a test in the operation of apparatus 20, in which carriage 48
2 reacts rearwardly under the influence of the extended or uncoiled constant-
3 force coiled spring members 40 re-coiling, hydraulic cylinder 105 absorbs
4 the force of the piston rod 104 striking closed door 108. Consequently,
5 with piston rod 104 abutting door 108, carriage 48 comes to a halt or stop
6 about six (6) inches from its O-position relative to frame 24 due to the
7 absorption by cylinder 105 of the force of impact of rod 104 on door 108.
8 Then by manually raising lever 110, door 108 rotates out of abutment with
9 hole 106 and thereafter, piston rod 104 is able to project through hole
10 106, with carriage 48 sliding along tubular members 26 until stops 101, 102
11 seat or abut one another. Thereafter by manually raising lifting knob 100,
12 end 82 of bell-crank assembly 81 can reach its ledge 83 to again place
13 apparatus 20 in its O-position illustrated in FIGS. 1 and 3.
14

15

16 The O-position of apparatus 20 prepares it for measuring the co-
17 efficient of friction of the road surface 78 upon release of cocking
18 mechanism 80 and the dropping of rotating tire 60 onto road 79 as a result
19 of such release. A straight, flat gauged tape 116 extends from its one
20 secured end 117 into rear metal casting 39 of frame 24 towards metal casting
21 28 to which it is connected by a spring 118 that maintains tape 116 in a
22 straight and flat manner for the purpose of obtaining a reading on one of
23 the measured graduations 120, along tape 116 in the operation of apparatus
24 20. Both planes, vertical and horizontal of tape 116, are parallel to the
25 corresponding vertical and horizontal planes for tubular members 26 and
26 tubings 47 of carriage 48 so that an accurate reading on tape 116 occurs in
27 a testing operation.
28

29 Tape 116 cooperates with an indicator 122, FIG. 1, in the form of
30 a collar, slidably mounted on the one tubular member 26 adjacent to it.
31 Indicator 122 works with carriage 48 in a testing operation. It is initially
32 set against a reference point 123 at the beginning of a test, the reference
33 point being provided by its associated bearing carrier 59, FIG. 1, while
34 being slidably mounted along the one tubular member 26. As carriage 48
35 shoots forward on tubular members 26 in a testing operation, reference
36 point 123 also correspondingly shoots forward, carrying forward as well
37 indicator 123 abutting against it in such movement. At the extreme point

1 of thrust for carriage 48 in its forward movement, indicator 123 remains at
2 such extreme extent pointing to a correlative reading on the adjacent tape
3 116 while the constant-force coiled springs 40 retract carriage 48 and all
4 the bearing carriers 59.

5

6 Circuit Description and Operation

7 Activation of electronic circuitry 22, FIG. 7, elements of the
8 circuitry being suitably supported in console 31, and from which console
9 31 separate wirings 33 extend to the electrical components in apparatus
10 20 which functions through its particular wiring 33, controls the process
11 of operation of apparatus 20 in a testing for the co-efficient of friction on
12 a road surface 78 of road 79. Description and explanation of operation of
13 the circuitry, FIG. 7, follows.

14

15 The following describes only the Positive (+) side of the circuitry.
16 Negative (-) leads are omitted for simplicity. And negative leads not
17 shown return to ground and/or the negative terminal of the power source.

18

19 Electric power (12V DC+) enters the circuit Master Fuse (F-1) [#
20 8 +9] and continues to the following:

- 21 1. Normally Open (NO) terminal of Contactor C1 [#2].
- 22 2. Normally Open (NO) terminal of Contactor C2 [#2].
- 23 3. Control Circuit Fuse (F2) [# 6 + 7].

24 Control Fuse F2 is connected to a key-operated On/Off switch SW1
25 [#4]. The closing of SW1 arms the circuit and provides power to the
26 following:

- 27 1. Push-button Momentary Switch SW2 [#3].
- 28 2. Power Input Terminal (12V +) of the Control Module CM1
29 [#1].
- 30 3. Normally Open (NO) Terminal of Switch A of Latch Relay 1
31 (R1A) [#14 + 15 +16].
- 32 4. Coil Terminal C of Off Delay Timer R1TD [#14 + 15 + 16] of
33 Latch Relay R1.

34 Momentary closing of SW2 begins a cycle by providing power to
35 the following:

- 1 1. Common Terminal (Com) of the output section of CM1.
- 2 2. Common Terminal (Com) of Switch A of Latch Relay 1 (R1A).
- 3 Through the Com Terminal of CM1, power is provided, within
- 4 CM1 to its Normally Closed (NC) Terminal and from it, to:

- 5 1. Shunt Terminal (S) of R1TD.
- 6 2. Coil windings of Motor/Clutch Contactor C1.

7 Upon receiving power at S, R1TD conducts power from C to the R1
8 coil [# 14], causing both of the R1A and R1B [# 14 + 15 + 16] switches
9 to transfer from Normal position to the Not-Normal position, resulting in
10 the following two events:

- 11 1. The transfer of R1A provides a pathway for power to COM of
12 CM1, bypassing SW2. This establishes a latch, keeping the R1 coil
13 energized and both R1A and R1B switches in the Not-Normal position.
- 14 2. The transfer of R1B breaks a connection to ground at the CM1
15 Reset terminal.

16 Upon receiving power, the coil of C1 energizes and the C1 NO
17 contacts are closed, providing power to the drive motor (M1) [#12] and
18 electric clutch (CL1) [#11], beginning the acceleration of the drive wheel.
19 As M1 accelerates, the SENSOR [#13] senses the movement of the motor
20 pulley and provides a digital signal that is proportional to the speed of M1
21 to the Sensor input of CM1. CM1 analyzes this signal and compares it to
22 a programmed value. At the moment that the measured value equals or
23 exceeds this programmed value, CM1 causes its output to transfer from
24 Normal and to latch in the Not-Normal state, removing power from its NC
25 terminal and supplying power to its NO terminal, leading to the following
26 events:

27 1. Removing power from NC terminal of CM1 removes power
28 from C1. Its contacts return to the NO state and power is removed from
29 M1 and CL 1.

30 2. When power is removed from terminal S of R1TD, a time delay
31 function commences which causes power to continue to be supplied to coil
32 R1 for approximately one (1) second, continuing the R1 latch

33 3. Providing power to the NO terminal of CM1 provides power to
34 the coil of Solenoid Contactor 2 (C2), which becomes energized, closing
35 the C2 NO contacts and energizing the Dropping Solenoid (SOL1) [#10].

36 37 ///

2 When the approximately one (1) second time delay of R1TD is
3 satisfied, the coil of R1 is de-energized and switches A and B return to
4 Normal position, ending the R1 latch, removing power from the COM
5 terminal of CM1.

6
7 The return of R1B to normal provides a path to ground for the reset
8 terminal of CM1, unlatching it, returning CM1 to Normal. At this point,
9 the circuit is ready for another cycle that can be begun by the closing of
10 switch SW2.

11
12 The components illustrated in FIG. 7 and described in the above
13 description of operation of electronic circuit 22 are readily available
14 today by referring to the following chart which lists the components by
15 their commercial identifications. The first column of numbers in the chart
16 below correlates to the components/elements shown in the FIG. 7
17 schematic drawing and the second column indicates the number of each of
18 such components/elements in circuit 22.

6

7 In operation of apparatus 20 on road surface 78 of a road 79, and
8 incorporating the above description as part and parcel of the following
9 description of the operation of apparatus 20, layers of glycerine (not
10 shown) are first applied to flat 61 of tire 60 and to a patch of road surface
11 78 at which testing of flat 61 is to take place, to negate or remove factors
12 involving humidity, extraneous contaminants of the road surface and which
13 could affect an accurate and correct reading on tape 116.. Thereafter,
14 apparatus 20 is put into its O-position, FIGS. 1, 2 and 3, which is that :

15

16 a) apparatus 20 is set in a stationary mode by the connection of its
17 hitch assembly 32 to a fixed, i.e., a non-moving support structure, such as
18 a parked vehicle (not shown) to which assembly 32 is connected;

19

20 b) mechanism 80 is cocked by positioning end or latch 82 of bell-
21 crank assembly 81 upon ledge 83 at the rear of apparatus 20 ;

22

23 c) adjusting sleeve 85 and its ledge 86 by which, say, a one-quarter
24 (1/4") inch span 98, is established between flat 61 and road surface 78 ;

25

26 d) door 108 is open, using an upward action on door lever 110 to
27 provide projection of piston rod 104 past hole 106;

28

29 e) carriage 48 is positioned at the extreme rear of frame 24;

30

31 f) indicator 122 is seated against its reference point 123 on its
32 bearing carrier 59 that is part of carriage 48, with constant-force coiled
33 springs 40 coiled in their non-extended position on rear metal casting 39;
34 and

35 g) with console switch SW1 open.

36

37 ///

2 The key switch SW1 of electrical control circuit 22 is closed, and
3 the SW2 switch is closed. Motor 34 [M1] begins to accelerate, and
4 electric clutch 65 engages to cause tire 60 to rotate with its axle 63, and tire
5 60 begins to rotate. Timing sensor 75 senses the movement of the sprocket
6 wheel 71 and provides a digital signal that is proportional to the speed of
7 motor 34. The digital signal is transmitted into the sensor input of the
8 control module CM1 in circuit 22. CM1 analyses this signal and compares
9 it to a programmed value say, for example , the programmed value being
10 50 miles per hour [mph] in control module CM1. At the moment the
11 measured value of speed of the rotating tire 60 equals or exceeds the
12 programmed value of 50 mph, the control module CM1 causes its output
13 to transfer from Normal and to latch into a not-Normal state.

14

15 What now occurs in the non-Normal state is that :

16

17 a) motor 34 stops running and electrical clutch 65 is disengaged ;
18 b) the solenoid 94 of dropping mechanism 80 is energized, the
19 bell-crank mechanism 80 is actuated by reciprocating action of the
20 solenoid's control or pull rod 93 , and by which end or latch 82 is pulled
21 off of its ledge 83;

22 c) apparatus 20 drops the tire 60 to the road surface 78. [Note:
23 glycerine has been brushed onto the tire's tread.]

24 d) the momentum of tire 60 propels carriage 48 against the force
25 of the constant-force coiled springs 40, to the right in FIG. 1. The
26 momentum of the wheel 62 is damped by the force of these coiled springs,
27 and carriage 48 ceases its movement to the right in FIG. 1. Wheel 62 and
28 carriage 48 are retracted by the force of springs 40 until the piston rod
29 104 strikes the spring-biased closed door 108. In effect the piston rod 104
30 substantially cancels the collective force of springs 40.

31

32 However, in the carriage's movement to the right, the indicator's
33 collar has slid along its tubing to its advanced position that is correlated to
34 the gauge tape that is calibrated to the coefficient of friction of the road's
35 surface to the rubber tire. The test is concluded by reading the gauge tape
36 at the point of advancement or thrust of the indicator 122.

37

1
2 The driving and driven pulleys, FIGS. 2A, 2B, are selected to
3 provide a wheel speed at a programmed value of CM1, equal to, for
4 example, 50 mph. At this value, the testing apparatus includes a 22-toothed
5 and 30-toothed sprocket. The programmed value can be other than a 50
6 mph figure .

7
8 For the next testing operation, the unit is prepared to achieve its O
9 position by these procedures:

10
11 1. The rear of carriage 48 is manually raised by knob 100 and the
12 bell crank assembly 81 is re-set on ledge 83.

13 2. The door 108 is manually opened against the bias spring 112 so
14 that piston rod 104 passes through hole 106.

15 3. The indicator 122 is slid back to where it is once again against
16 its associated bearing carrier 59 of carriage 48.

17
18
19 Each of the components and elements of apparatus 20 is fabricated
20 from known materials using standard and conventional techniques of
21 manufacture. Assembly of apparatus 20 begins with assembly of the
22 elements forming the frame and its sub-components, then the carriage,
23 dropping mechanism, wheel assembly and electronic control systems, and
24 can be readily achieved by knowledge of this disclosure.

25
26 Various modifications, changes can be made in apparatus 20
27 without departing from the spirit and scope of the appended claims to the
28 invention.

29 INDUSTRIAL APPLICABILITY

30
31 The invention is useful in testing road surfaces such as although not
32 to be considered exhaustive, parking lot surfaces, sidewalks, airport
33 runways, street intersections, manhole covers, bridge plates, decking, slurry
34 coatings, asphalt, concrete, reprocessed road material, and roadway paint
35 products.

36
37 I claim:
